What are AI Native Operating Systems ?

Creating systems where agents and humans work together. For instance you can have roadmap software that allows your team to follow what tasks are suggests, in progress and done. Now, an AI agent could also interact with that system and do suggested tasks that are on the list. Then move these tasks to in progress, then up for review by a human and then finally to the done stage.

AI Native Workflow

The goal of AI agents will be to perform tasks on the internet on your behalf. Now, for this to work there need to be systems in place that can talk to these agents. Now, the data fed into these systems are also inserted by a combination of humans and other agents that get it again from other AI agents until it stops at the agent that has access to sensors to actually measure things in the real world.

We Still Need Apps and OS with a GUI

Even though AI agents don't need a GUI to operate, humans do need it to work together with the agents. We cannot remember all of the data in our heads. We do needs lists, summaries, overviews, folders, structure to make sense of things.

Custom OS for every company

You create an operating system that works specifically in particular sector that improves itself every day. Again, for global cooperation it would be great that you get the same systems for each sector. In that way it is easy to collaborate in different countries and learn from each other.
